Thermoplastics pipes for the conveyance of fluids –
Determination of the slow cracking resistance of pipes and
fittings using the Notched Ring Test (NRT)
(ISO/TS 16479:2012, IDT)
Standarder får världen att fungera

SIS (Swedish Standards Institute) är en fristående ideell förening med medlemmar från både privat och offentlig sektor. Vi är en del av det europeiska och globala nätverk som utarbetar internationella standarder. Standarder är dokumenterad kunskap utvecklad av framstående aktörer inom industri, näringsliv och samhälle och befrämjar handel över gränser, bidrar till att processer och produkter blir säkrare samt effektivisera din verksamhet.

Delta och påverka
Som medlem i SIS har du möjlighet att påverka framtida standarder inom ditt område på nationell, europeisk och global nivå. Du får samtidigt tillgång till tidig information om utvecklingen inom din bransch.

Ta del av det färdiga arbetet
Vi erbjuder våra kunder valfri tillgång till alla publikationer, allt från enskilda standarder, tekniska rapporter och standardpaket till handböcker och onlinetjänster. Genom vår webbtjänst e-nav får du tillgång till ett lätt navigerat bibliotek där all standarder som är aktuella för ditt företag finns tillgängliga.

Ta del av det färdiga arbetet
Vi erbjuder våra kunder valfri tillgång till alla publikationer, allt från enskilda standarder, tekniska rapporter och standardpaket till handböcker och onlinetjänster. Genom vår webbtjänst e-nav får du tillgång till ett lätt navigerat bibliotek där all standarder som är aktuella för ditt företag finns tillgängliga.

Vill du veta mer om SIS eller hur standarder kan effektivisera din verksamhet är du välkommen in på www.sis.se eller ta kontakt med oss på tel 08-555 523 00.

Standards make the world go round

SIS (Swedish Standards Institute) is an independent non-profit organisation with members from both the private and public sectors. We are part of the European and global network that draws up international standards. Standards consist of documented knowledge developed by prominent actors within the industry, business world and society. They promote cross-border trade, they help to make processes and products safer and they streamline your organisation.

Take part and have influence
As a member of SIS you will have the possibility to participate in standardization activities on national, European and global level. The membership in SIS will give you the opportunity to influence future standards and gain access to early stage information about developments within your field.

Get to know the finished work
We offer our customers everything in connection with standards and their application. You can purchase all the publications you need from us - everything from individual standards, technical reports and standard packages through to manuals and online services. Our web service e-nav gives you access to an easy-to-navigate library where all standards that are relevant to your company are available. Standards and manuals are sources of knowledge. We sell them.

Increase understanding and improve perception
With SIS you can undergo either shared or in-house training in the content and application of standards. Thanks to our proximity to international development and ISO you receive the right knowledge at the right time, direct from the source. With our knowledge about the potential of standards, we assist our customers in creating tangible benefit and profitability in their organisations.

If you want to know more about SIS, or how standards can streamline your organisation, please visit www.sis.se or contact us on phone +46 (0)8-555 523 00

This Technical Specification is not a Swedish Standard. This document contains the English version of ISO/TS 16479:2012.

Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

In other circumstances, particularly when there is an urgent market requirement for such documents, a technical committee may decide to publish other types of document:

- an ISO Publicly Available Specification (ISO/PAS) represents an agreement between technical experts in an ISO working group and is accepted for publication if it is approved by more than 50 % of the members of the parent committee casting a vote;
- an ISO Technical Specification (ISO/TS) represents an agreement between the members of a technical committee and is accepted for publication if it is approved by 2/3 of the members of the committee casting a vote.

An ISO/PAS or ISO/TS is reviewed after three years in order to decide whether it will be confirmed for a further three years, revised to become an International Standard, or withdrawn. If the ISO/PAS or ISO/TS is confirmed, it is reviewed again after a further three years, at which time it must either be transformed into an International Standard or be withdrawn.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO/TS 16479 was prepared by Technical Committee ISO/TC 138, Plastics pipes, fittings and valves for the transport of fluids, Subcommittee SC 5, General properties of pipes, fittings and valves of plastic materials and their accessories — Test methods and basic specifications.
Introduction

At the present time ISO/TC 138 provides several test methods for determining the resistance to slow cracking which are essential for assessing properties and durability of thermoplastics pipes and fittings. In fact, they constitute a basis for determining the long term performance characteristics of these parts. In line with the development of better slow crack resistant materials, new accelerated test methods for evaluating slow crack resistance of thermoplastic piping parts are frequently under investigation [1-3]. In consideration of this, the Notched Ring Test (NRT) method has been developed and applied to determine its applicability as the standard test method and has demonstrated its effectiveness in generating slow cracking within the time frame of interest [4-7]. This Technical Specification provides details of the NRT method in terms of test implementation, its SCG performance evaluation, and the application of the method utilizing the stress intensity factor approach.
Thermoplastics pipes for the conveyance of fluids — Determination of the slow cracking resistance of pipes and fittings using the Notched Ring Test (NRT)

1 Scope

This Technical Specification determines the slow cracking resistance of pipes and fittings using the Notched Ring Test (NRT) which is a method for determining the slow crack resistance of thermoplastics resins and compounds in pipe form and/or finished products (e.g. pipes and fittings) from which a ring specimen can be cut and notched. The test is performed under sustained constant loading in a test medium at a specified temperature and the time to the on-set of slow cracking is measured. This method applies to the rings from pipes or fittings having a wall thickness greater than 5 mm. This Technical Specification specifies the method of testing using notched ring specimens directly obtained from pipes or fittings.

2 Normative references

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO 6108, Double equal angle cutters with plain bore and key drive
ISO 13479, Polyolefin pipes for the conveyance of fluids — Determination of resistance to crack propagation — Test method for slow crack growth on notched pipes (notch test)

3 Terms and definitions

3.1 slow crack growth
SCG

crack growth that occurs below the critical stress intensity factor at which the unstable rapid crack propagation takes place

NOTE The crack growth is stable and hence can grow to a substantial length before causing material to fail either by rapid fracture or ligament yielding. In some polyolefin materials, distinct fracture surface features characteristic of slow crack growth are apparent and are often used as an indicator of slow crack growth

3.2 ring deflection curve
time dependent deflection curve obtained from the sustained constant flexure loading of the ring specimen

NOTE 1 See Annex A.

NOTE 2 The curve may have similar features of a creep curve, normally consisting of primary, steady state secondary and tertiary regions. Deflection is normally taken at the notch position and directly above the line of load application.

3.3 on-set slow cracking time

$t_i$ (h)
time for first noticeable abnormal change to appear on the recorded ring deflection curve

NOTE 1 See Annex A.
NOTE 2 For this definition to be complete, the fracture surface must show features of slow cracking in any degree or features defined otherwise.

EXAMPLE Examples of abnormal change are discontinuity, slope change etc.

3.4 applied load
\( L \) (N)
load applied in three point flexure mode

3.5 applied stress intensity factor
\( K_0 \) (N/m\(^{3/2}\))
crack-tip stress intensity factor calculated based on the initial notch dimension

4 Principle

A suitable NRT specimen is an undisturbed full ring of certain width directly removed from the pipes or fittings (see Figure 1), having features that include an inner wall notch along the sample width between the tips of two coplanar sidewall notches (see Figure 5). The inner wall and sidewall notches are all in the same plane and the notch and specimen dimensions are such that conditions for the plane-strain slow crack growth are met at the notch tip. Coplanar sidewall notches are introduced to further maintain the plane strain condition as well as to act to guide the loading rod accurately along the line of the crack tip. NRT specimens are subjected to sustained and constant flexure load in a temperature controlled medium and the time to on-set cracking as defined in 3.3 is determined from the measured ring deflection curve (see 3.2 and Annex A). In the NRT specimen, the slow cracking can be initiated in a relatively shorter time due to the possibility of constrained crack tip deformation induced by the sample and the loading geometry, hence allowing higher stress intensity to develop at the crack tip without gross yielding.
5 Apparatus

5.1 Loading apparatus

A suitable device for loading the ring specimen in a sustained and constant manner under flexure mode shall be used. The device may utilize dead weights, pneumatically actuated loading or any other means for producing a sustained constant load with accuracy better than ±1,0 % of the applied load. The loading, supporting and guiding rods (see Figure 1) are made from a 316 stainless steel having the same ground surface and they are positioned parallel to each other. The guiding rod guides the loading rod right on top of the inner wall notch by means of adapting the sidewall notches (see Figures 1 and 5). An impression of a typical loading jig is shown in Figure 2.

5.2 Ring deflection measuring device

Ring deflection of the mid-span containing the plane of the crack front (see Figure 1) shall be measured by means of a suitable device that will not influence the specimen in any way. Particular caution should be practiced to ensure the stability of the measuring device with time, temperature and humidity. The device shall be capable of deflection measurement with accuracy better than ±1,0 % and a resolution of 0,01 mm. Since it is important to continuously monitor the deflection, it is recommended to use an automatic deflection measuring system. An example of an electronic displacement gauge and its assembly to an overall loading-measuring device is shown in Annex A. The measurement shall not be influenced by any mechanical and/or electric disturbances that may end up in the deflection curve being obtained.

Figure 1 — The diagram and loading configuration of NRT specimen
